

**Hardy vegetables** tolerate hard frosts (usually 25 to 28 degrees F). The hardiest—kale and spinach—can tolerate temperatures in the low 20s and high teens. Harvest can extend into winter. Our last frost date is on average May 20, and our first frost in the fall is on average September 20. Many of these hardy vegetables will continue in the garden for weeks after the first hard frost.

- Broccoli – good for spring and fall
- Cabbage – good for spring and fall
- Peas – good for spring and fall
- Kale – one planting will provide a continuous harvest from spring through fall
- Radish – plant every two weeks spring through August
- Spinach – plant every two weeks spring through August

**Semi-hardy vegetables** tolerate light frosts (usually 29 to 32 degrees F). They are good for spring and fall gardens.

- Beets – plant successions throughout spring, again in June for a fall crop
- Carrot – plant successions throughout spring, again in June for a fall crop
- Potatoes
- Lettuce and salad greens – plant every two weeks early spring through August

**FOR SUMMER:** Plant after the threat of frost is past. These tender vegetables need warm weather (65 to 90 degrees F) to grow and are killed by frost. They are for summer gardens only. Plant as soon as weather is warm to ensure harvest before fall frost.

- Beans – can plant twice
- Corn
- Summer squash
- Cucumber – can plant twice
- Tomatoes
- Melons
- Peppers
- Winter Squash

# Crop Rotation

Crop rotation is a strategy that can help keep your garden healthy and increase your overall production significantly by preventing some common problems attributable to planting the same crop in the same place year after year such as depletion of specific soil nutrients and increases in pest and disease pressure.

It involves changing where in your garden you grow different types or families of crops.

## Examples of Different Plant Families in the Garden:

- Solanaceous Crops: tomatoes, eggplant, peppers, potatoes
- Legumes: beans and peas and legume cover crops such as vetch and clover
- Cucurbits: cucumber, squash, melons, pumpkins
- Brassicas: cabbage, cauliflower, broccoli, kale, turnips, radish, mustard, collards
- Carrot Family: carrots, parsnips, celery, dill, cilantro, parsley, caraway, fennel
- Asters: sunflowers, lettuce, endive, radicchio, Jerusalem artichoke, artichoke
- Alliums: asparagus, onions, leeks, chives, garlic, shallots

## To reduce the pressure from pests and diseases

- Members of different plant families often share pests and diseases which will thrive if the same plants are in the same space year after year. These garden menaces will build up on a given site over time if you do not rotate your crops. Moving your plant families from place to place in the garden helps break up the life cycles of harmful organisms.

## To maintain adequate fertility

- Specific crops often use some nutrients more than other, so if you plant the same crop in the same place, the soil on that site can quickly be depleted of specific nutrients.
- Some crops are heavy feeders, meaning they require high levels of fertility while other crops need less fertility to thrive. Growing heavy feeders in the same place from year to year will deplete soil fertility and quickly impact the health of your plants.

## Crop Rotation Planning

The most effective way to plan crop rotations is to plan three or more years ahead. This sounds like a lot, but when you consider it in terms of how many planting successions take place in that period, it starts to make sense. The best practice is have a crop family in a bed for one succession, and then keep that bed free of that family for two years to break up pest and disease life cycles.

## Consider:

- The space requirements for each crop you will grow
- The family of the crop you are growing
- Your crop's fertility needs
- How and when you will incorporate soil building practices like cover crops into your rotation
